

# Elements of The Same Type

```
<div  
  className="before"  
  title="noice"  
>
```

```
<div  
  className="after"  
  title="noice"  
>
```

By comparing these two elements, Reconciler specifies what is going to be changed.

In this case, React-DOM knows how to only modify the className on the underlying DOM node.

# Component Elements of The Same Type

The instance stays the same, so that state is maintained across renders.

```
<div>Niceeee</div>    <div>Dude!</div>
```
